Abstract

Following the high integrated luminosity accumulated in the first two Pb-Pb collision runs in 2010 and 2011, the LHC heavy-ion physics community requested a first run with p-Pb collisions.

This almost unprecedented mode of collider operation was not foreseen in the baseline design of the LHC whose two-in-one magnet design imposed equal rigidity and, hence, unequal revolution frequencies, during injection and ramp. Nevertheless, after a successful pilot physics fill in 2012, the LHC provided 31 nb⁻¹ of p-Pb luminosity per experiment, at an energy of 5.02 TeV per colliding nucleon pair, with several variations of the operating conditions, in early 2013. Together with a companion p-p run at 2.76 TeV, this was the last physics before the present long shutdown.

We summarise the beam physics, operational adaptations and strategy that resulted in extremely rapid commissioning. Finally, we give an account of the progress of the run and provide an analysis of the performance.

RF Frequency for p and Pb in LHC

$$f_{\rm RF} = \frac{h_{\rm RF}}{T\left(p_{\rm p}, m, Q\right)} \quad , \quad T\left(p_{\rm p}, m, Q\right) = \frac{C}{c} \sqrt{1 + \left(\frac{mc}{Qp_{\rm p}}\right)^2 (1 + \eta\delta)}, \quad h_{\rm RF} = 35640 \text{ in LHC}$$

LHC has independent RF systems in each ring.

Equal $f_{\rm RF}$ at injection

 $\Rightarrow \pm 35$ mm orbit displacement in arcs Must ramp with unequal $f_{\rm RF}$

- ⇒ long-range beam-beam encounters are moving
- \Rightarrow kicks vary from turn-to-turn
- \Rightarrow modulated beam-beam kicks
- \Rightarrow possible instability, emittance growth

At top energy, 4Z TeV in 2012-13, it is possible to equalise revolution frequencies with equal and opposite ± 0.3 mm displacements of the proton and lead beams. Can only do this after ramp.

RHIC D-Au in 2003 (PAC'2003, TPPB043)

Initial attempts with equal rigidity, unequal frequencies as in LHC

- "modulated long-range beam-beam forces created untunable beam loss"
- Doubts of feasibility for LHC; not part of LHC TDR

RHIC: Independent bending field for the two beams – switched to equal-frequency injection and ramp for successful D-Au operation.

LHC: Identical bend field in both apertures of two-in-one dipole – no choice!

J.M. Jowett, International Particle Accelerator Conference, Shanghai, 13 May 2013

History and preparations for p-Pb physics

2005 CERN workshop on pA in LHC

- Predicted that p-Pb in LHC could work
- Detailed physics case written up
- 2010-11 first two Pb-Pb runs of LHC make 10 $\mu b^{-1} + >150 \mu b^{-1}$
 - Urgent need for p-Pb comparison data (30 nb⁻¹)
 - Request from ALICE considered, early 2011
- Detailed review and adaptation of all LHC systems, machine protection, operational procedures
- Feasibility test 31 October 2011
- Go-ahead for further tests and pilot run in 2012
 - But all machine study time in 2012 lost for various reasons ...

First asymmetric collisions at LHC

2012 PROTON-LEAD PILOT RUN

Concept

Take LHC through the new operational sequence for physics for the first time

- Provide experiments with first useful physics data to set up their triggers in advance of production run a few months later
- Beam parameters (no squeeze, few bunches) chosen to allow shortest possible set-up and yet satisfy machine protection requirements in the course of a typical LHC machine study period (16 h allocated)

Pilot p-Pb run, night of 13-14 September 2012

- 16:00 Starting injection, problems with ions, timing events not sent out correctly.
- 18:30 Filling Pb ions, first time in 2012
- 19:00 Start of ramp. Lost the beam on TCT position interlocks, revert collimator settings and try again
- QPS problems. RF problems.
- 22:52 15 p and 15 Pb bunches at 4 Z TeV, 8 colliding per experiment, 3 sacrificial for collimation setup
- 23:35 Beams in collision, unsqueezed, optimising ...
- 00:50 Start of loss maps to set up collimation
- 01:26 Stable beams for p-Pb Physics
- 06:04 Adjust mode to move IP for ALICE
- O6:25 Stable beams again, IP moved by -0.5 m
- O7:55 Stable beams again, IP moved by +0.5 m
- 09:35 Beams dumped by operators

Physics requests for the 2013 p-Pb run

Initial minimum bias p-Pb for ALICE

 $\frac{L_{\text{ALICE}} < 0.05 \times 10^{29} \text{ cm}^{-2} \text{s}^{-1}}{\mu_{\text{ALICE}} < 0.003} \text{ at } \sqrt{s_{\text{NN}}} = 5.02 \text{ TeV (}4Z \text{ TeV/beam)}$

□ Integrate 30 nb⁻¹ in ALICE respecting the constraints:

 $L_{\rm ALICE} < 1. \times 10^{29} {\rm ~cm}^{-2} {\rm s}^{-1}$ ~ 30000 pilot runs $\mu_{ALICF} < 0.05$

- Similar (or more) luminosity in ATLAS and CMS
- Beam reversal p-Pb to Pb-p for ALICE, LHCb
- 2 ALICE polarity reversals (also LHCb)
- \Box Few nb⁻¹ in LHCb (new to heavy-ion operation)
- Van der Meer (luminosity) scans
- 2nd priority: intermediate energy p-p operation
 - $\sqrt{s_{NN}} = 2.76 \text{ TeV} (1.38 \text{ TeV/beam})$ Integrate 5 nb⁻¹ in ATLAS, CMS
- 3rd priority: p-Pb with injection optics for LHCf
 - About 1 day required to commission and run

both p-Pb and intermediate energy p-p.

Commissioning p-Pb operation, January 2013

- Still no test of unequal frequency injection ramp with required intensity ... factor 1000 in luminosity to gain over pilot run
- From ~cold start after end-of-year stop
 - Pb pre-injectors kept running
 - → D. Manglunki et al, WEPEA061, Wed
 (remarkable performance of Pb injectors later!)
- Detailed plan of essential stages, adapted in real time
 - Decided to re-make optics squeeze from scratch (new low values in ALICE, LHCb)
 - Off-momentum collisions, many new features
 - New collimation set-up
 - \rightarrow **R. Versteegen et al, TUPFI041, Tue**
- Unprecedented new operation mode of LHC commissioned in < 10 days (including ~4 days down-time for power, cryo)
 - Quality of LHC hardware, systems, operation

The Moment of Truth, finally, 20/1/2013

Fill 3474

First injection and ramp of Pb trains against proton trains

Moving long-range beam-beam encounters do not cause significant beam losses or emittance blow-up with LHC parameters

120

Full filling scheme 21/1/2013

During commissioning

- Pb-p Intensity ramping was delayed by several dumps caused by losses at the start of cogging, when the two beams are brought to the same frequency
- Losses were reduced by making a slower frequency trim (3 steps of 10 Hz max, and 10 s waiting time in between)
- The BLM beam dump threshold was increased in selected BLMs. This was also needed to cope with losses in squeeze and start of ramp
- All problems were in the Pb ring, probably linked to the lower collimation efficiency
- Ring 2 was somewhat less "touchy".
 - p-Pb caused fewer problems than Pb-p

Horizontal position B1 and B2. Visible are the three steps (~ 10 Hz each) with the 10 s waiting. The following triangle brings the intersection point (IP) in the exact center of the detectors. To achieve this, the beams are briefly brought back to the center orbit.

RF "cogging" during and after energy ramp

- We monitor the time interval between the revolution frequency markers (bucket 1 of both rings)
- Cogging takes 15 minutes maximum
- Fully automatic. The references were calibrated at the beginning of the run and not touched during the four

weeks

Ramping

IP close to desired position, we move the beams to the common frequency

Run overview: Pb-p luminosity production

Peak and integrated luminosity evolution

- Full instantaneous luminosity 1x10²⁹ cm⁻².s⁻¹ already reached with the first fill with full filling scheme
- Levelling in ALICE at 1x10²⁹ cm⁻².s⁻¹ in almost all standard fills
- Two catch-up fills done with IP1 and 5 separated, allowing ALICE to catch up after initial minimum-bias
- Van der Meer scans done in both configurations
- Final integrated luminosity above experiments' request of 30 nb⁻¹
- The run ended with record peak luminosity of 1.15x10²⁹ cm⁻².s⁻¹, record turn around of 2.37 h

CMS: 31.69 nb⁻¹ LHCb: 2.12 nb⁻¹

J.M. Jowett, International Particle Accelerator Conference, Shanghai, 13 May 2013

Luminosity evolution during a fill

- Luminosity evolution was driven by Pb intensity decay.
- Sources of losses were mainly luminosity burn-off and intra-beam scattering (IBS), possibly also beam-beam (unequal beam sizes in collision)
- Additional losses at start of stable beams are comparable to Pb beam BLM signals, likely due to tight collimator settings.

J.M. Jowett, International Particle Accelerator Conference, Shanghai, 13 May 2013

Pb intensity evolution, fill duration

- Injectors provided very good quality Pb beams: average number of ions per bunch was 1.44x10⁸ at start of stable beams (mean over the run), i.e. almost twice the nominal intensity,
- Most fills were dumped by the BPMSs thresholds in IR6 due to misreading for lowest intensity Pb bunches
- BPMSs' limit was reached faster with B1 (Pb-p) than with B2 (p-Pb),
- Maximum fill durations of more than 10h were reached with intermediate filling schemes and special fills colliding only in ALICE (and LHCb).

J.M. Jowett, International Particle Accelerator Conference, Shanghai, 13 May 2013

Peak performance in p-Pb runs

	2012 pilot	2013 production	
E/(Z TeV)	4	4	
k _c	(8,8,8,8)	(296,288,296,39)	
β */m	(11,10,11,10)	(0.8,0.8,0.8,2.0)	
$\gamma \epsilon(p)/\mu m$	1.7	2	
γε(Pb)/ μm	1.2	1.5	
N_{bp}	1.2×10^{10}	1.6×10^{10}	
$N_{b m Pb}$	7×10^{7}	12×10^{7}	
$L/(10^{29} \mathrm{cm}^{-2} \mathrm{s}^{-1})$	0.001	(1.12,1.01,1.16,0.05)	

- Some numbers are averages because of the wide distribution of individual bunch parameters.
- Sets of four values correspond to the interaction points IP1(ATLAS), IP2(ALICE), IP5(CMS), IP8 (LHCb).

Summary of first LHC p-Pb run

- A new mode of operation, unforeseen in the baseline design of the LHC, was commissioned in 10 days (including >4 days' down time).
- The physics requirements were fulfilled in both configurations p-Pb and Pb-p
- □ ALICE, ATLAS, CMS, LHCb, ALFA, TOTEM, LHCf all took data.
- Pb beam from injectors: very high quality, new intensity records.
- No serious beam-beam effects thanks to low proton beam intensity, allowing us to break a few rules (only way to give LHCb collisions).
- Proton beam intensity could not be increased because of bad readings on beam-dump interlock BPMs at their sensitivity limit.
- No clear effects of moving long-range beam-beam encounters at injection and ramp.
- Duration of fills given by strong luminosity burn-off and IBS.
- Beam loss monitor dump thresholds were pushed to theoretical quench limits, losses might have been reduced with more relaxed (=more open) collimator settings.
- Lack of emittance measurement capability during run
- Many other features not described here ...
- Prospect of about another order of magnitude in luminosity in future LHC runs at higher energy

PROTON-NUCLEUS PHYSICS: FLAT TOP

Proton-lead run brings new physics reach to LHCb

Antonella del Rosso

During the recent lead-proton run at the Large Hadron Collider (LHC), the Large Hadron Collider beauty (LHCb) experiment took data from collisions between protons and ions for the first time.

Why unequal frequencies?

- The two LHC rings see n identical strength but opposite sign magnetic field
- The two RF systems are n independent
 - At injection we have 4.7 kHz difference between the two rings (at 400 MHz)
 - At the end of the 4 TeV ramp the difference is 60 Hz only
- On flat top we lock the two n rings on the same frequency, resulting in a +0.3 mm offset of the p ring and -0.3 mm offset of Pb ring
- We then gently cog the two n rings to achieve crossing in the detector. It takes 11 minutes maximum for the 27km long ring. The intersection point moves around Pays de Gex at ~150 km/h!

ATLAS BPTX from end-ramp to endrephasing. Measures the time interval between passage of bucket 1 of both rings in the detector

during the ramp

Same frequency 60 Hz difference at 4.7 kHz end of ramp difference at Frequency ring 1 injection (proton) in green and ring 2 (Pb) in yellow

Beam performances over the run – emittances

- Wire scanners available during commissioning and Pb-p modes,
- BGI available for B2,
- BSRTs signal at injection very low \rightarrow set to mean over the bunches,
- Absolute calibration very difficult for all measurements,

J.M. Jowett, International Particle Accelerator Conference, Shanghai, 13 May 2013

Already close to ALICE maximum luminosity with emittances of pilot fill, good Pb intensity, fairly conservative proton intensity – leaves room to try to increase it up to a factor ~3 (level ALICE if necessary).

Can easily be worse if we have blow-up or losses at injection or ramp (from moving encounters, IBS, ...).

Unequal beam sizes were OK in pilot fill with higher β^* . Emittance increase will probably reduce luminosity for all experiments and pile-up for ALICE.

This is our preferred first goal for the run. But, on the basis of present knowledge, it is by no means a "safe set of parameters" (except for optics).

J.M. Jowett, LHC Machine Committee 30/1/2013

Proton intensity could not be increased further than 1.8x10¹⁰ charges because of BPMs bad readings (injection of 3x10¹⁰ p/bunch was tested on 17/01/2013),

•

- No obvious effects observed due to moving encounters at injection and during the ramp,
- Low intensity beams allowed us to get around beam-beam effects related to unequal beam sizes, or small separation for 'bad' polarity of ALICE...

Beam-beam effects

... but still beam-beam effects were there.

LHCb bunches in p-Pb configuration had parasitic encounters at small separation in IR2 ($\approx 1\sigma$) and suffered more than the others from a small J.M. Joint interempting (fill at 3509). Shanghai, 13 May 2013

Openings for future ion runs – batch by batch blow up at injection 2/2 Compare Best with Average Bunc

- Batch by batch blow up to 1.4 1.6 ns at injection was tested to reduce IBS effect on transverse emittances,
- No clear effect on p-Pb luminosity,
- No clear conclusion from beam size measurements yet, analysis on going. IBS simulations results for 1.4 – 1.5 ns bunch length (M. Schaumann):
- Horizontal emittance growth is slowed down by >10% after 30min
- Vertical emittance is not affected (as expected)
- Losses are enhanced for Diown up bunches Sapinski, M. Schaumann by about ~5% after 30min

Choice of operating energy for p-Pb in 2012

Charges Z_1, Z_2 in rings with magnetic field set for protons of momentum p_p : colliding nucleon pairs have:

$$\sqrt{s_{NN}} \approx 2c p_p \sqrt{\frac{Z_1 Z_2}{A_1 A_2}},$$
$$y_{NN} = \frac{1}{2} \log \frac{Z_1 A_2}{A_1 Z_2}$$

2.2 Z TeV "ideal" but would cost factor ~6-7 in integrated luminosity and exceeds 1 mm orbit limit in LHC arcs.

4 Z TeV, the final choice for 2012, will be "easiest" from accelerator point of view.
